INTRODUCTION

This HP-41C Solutions book was written to help you get the most from your calculator. The programs were chosen to provide useful calculations for many of the common problems encountered.

They will provide you with immediate capabilities in your everyday calculations and you will find them useful as guides to programming techniques for writing your own customized software. The comments on each program listing describe the approach used to reach the solution and help you follow the programmer's logic as you become and expert on your HP calculator.

KEYING A PROGRAM INTO THE HP-41C

There are several things that you should keep in mind while you are keying in programs from the program listings provided in this book. The output from the HP 82143A printer provides a convenient way of listing and an easily understood method of keying in programs without showing every keystroke. This type of output is what appears in this handbook. Once you understand the procedure for keying programs in from the printed listings, you will find this method simple and fast. Here is the procedure:

1. At the end of each program listing is a listing of status information required to properly execute that program. Included is the SIZE allocation required. Before you begin keying in the program, press **XEQ** **ALPHA** SIZE **ALPHA** and specify the allocation (three digits; e.g., 10 should be specified as 010).

Also included in the status information is the display format and status of flags important to the program. To ensure proper execution, check to see that the display status of the HP-41C is set as specified and check to see that all applicable flags are set or clear as specified.

2. Set the HP-41C to PRGM mode (press the **PRGM** key) and press **▀** **GTO** **◻** **◻** to prepare the calculator for the new program.
3. Begin keying in the program. Following is a list of hints that will help you when you key in your programs from the program listings in this handbook.
 - a. When you see " (quote marks) around a character or group of characters in the program listing, those characters are ALPHA. To key them in, simply press **ALPHA**, key in the characters, then press **ALPHA** again. So "SAMPLE" would be keyed in as **ALPHA** "SAMPLE" **ALPHA**.
 - b. The diamond in front of each LBL instruction is only a visual aid to help you locate labels in the program listings. When you key in a program, ignore the diamond.
 - c. The printer indication of divide sign is /. When you see / in the program listing, press **÷**.
 - d. The printer indication of the multiply sign is ✖. When you see ✖ in the program listing, press **×**.
 - e. The † character in the program listing is an indication of the **APPEND** function. When you see †, press **▀** **APPEND** in ALPHA mode (press **▀** and the K key).
 - f. All operations requiring register addresses accept those addresses in these forms:
 - nn (a two-digit number)
 - IND nn (INDIRECT: **▀**, followed by a two-digit number)
 - X, Y, Z, T, or L (a STACK address: **◻** followed by X, Y, Z, T, or L)
 - IND X, Y, Z, T or L (INDIRECT stack: **▀** **◻** followed by X, Y, Z, T, or L)

Indirect addresses are specified by pressing **▀** and then the indirect address. Stack addresses are specified by pressing **◻** followed by X, Y, Z, T, or L. Indirect stack addresses are specified by pressing **▀** **◻** and X, Y, Z, T, or L.

TABLE OF CONTENTS

1. FORECASTING USING EXPONENTIAL SMOOTHING.....1
This program is a singly-smoothed exponential forecasting routine with consideration for seasonal variation.
2. MONTHLY SEASONAL VARIATION FACTORS BASED ON CENTERED MOVING AVERAGES.....8
(Develops seasonal variation factors based on historical figures.)
The factors are useful for projecting seasonal sales.
3. MULTIPLE LINEAR REGRESSION.....13
Linear regression for one dependent and two independent variables, using the least squares method.
4. NORMAL, INVERSE NORMAL, t AND F DISTRIBUTIONS.....20
These programs evaluate the standard normal density function, the normal integral for a given x and its inverse, the t density function, and the integral of the F distribution for given values of x .
5. BASIC STATISTICS FOR TWO VARIABLES.....33
Calculates means, standard deviations, covariance, correlation coefficient, and coefficients of variation from a set of grouped or ungrouped data points.
6. MOVING AVERAGE.....40
Calculates one or more different moving averages from a single set of data. Allows data storage if card reader is available.
7. GOMPERTZ CURVE TREND ANALYSIS.....48
Program fits data to a Gompertz curve and calculates estimated values for future data points. The sales curves for many products follow this trend during the introductory, growth and early mature phases.
8. BREAK-EVEN ANALYSIS.....53
Calculates all values for linear break-even chart.
9. EXPERIENCE (LEARNING) CURVE FOR MANUFACTURING COST...59
Produces standard learning curve parameters useful in projecting production costs as a function of units produced.
10. PRICE OF ELASTICITY OF DEMAND.....64
Using historical (or estimated) prices and resulting sales, this program calculates the elasticity of demand.

FORECASTING USING EXPONENTIAL SMOOTHING

Exponential smoothing is a special kind of moving average. It is often used for short-term sales and inventory forecasts. Typical forecast periods are monthly or quarterly.

Unlike a moving average, exponential smoothing does not require a great deal of historical data. This program, for example, forecasts demand by using only a smoothing constant, an "old smoothed average," and a current-period usage statistic.

This program is a singly-smoothed exponential forecasting routine which: (1) accomodates quarterly seasonal correction factors, (2) can handle some trend in the data, (3) produces smoothed estimates of current demand, D_t , (4) produces next-period smoothed demand estimates, D_{t+1} , (5) calculates a mean absolute deviation, MD, and a tracking ratio, T , (6) provides a goodness of fit measure, V, which measures the variance between the next period's demand estimate to that period's actual demand, and (7) provides for convenient restarting when the user wishes to update a data series.

This program should not be used with data which has more than a moderate amount of up or down trend. And, at least two projections of D_{t+1} must be done before MD or T can be calculated.

Counter Q_i is used with the deseasonalizing adjustment option. Q_i keeps track of the fiscal quarter or calendar quarter associated with a given X_t , and should always be for time period $t-1$.

Equations:

α = smoothing constant ($0 < \alpha < 1$)

X_t = actual current period usage smoothed average,

$$S_t = \alpha X_t + (1-\alpha)S_{t-1}$$

change, $C_t = S_t - S_{t-1}$

$$\text{trend, } T_t = \alpha C_t + (1 - \alpha) T_{t-1}$$

$$\text{current period expected usage, } D_t = S_t + \frac{(1 - \alpha)}{\alpha} T_t$$

$$\text{forecase of next period expected usage, } D_{t+1} = S_t + \left(\frac{1}{\alpha}\right) T_t$$

error, $e = D_t - X_t$

$$\text{cumulative error} = \sum_{t=1}^m e^2$$

initial conditions: $S_{t-1} = X_{t-1}$

$$T_{t-1} = 0$$

SV = seasonal variation factor

MONTHLY SEASONAL VARIATION FACTORS BASED ON CENTERED MOVING AVERAGES

Seasonal variation factors are a useful concept in many types of forecasting. There are several methods of developing seasonal moving averages, one of the more common ways being to calculate them as the ratio of the periodic value to a centered moving average for the same period.

For instance, to determine the sales for the 7th month of a given year, a centered moving average for that month would be calculated from sales figures from the 1st thru 12th months of that year and the 1st month of the following year. The seasonal variation factor for the 7th month would then be the ratio of the actual sales in the 7th month to the centered moving average for that month.

Equations:

$$\bar{X}_c = \frac{X_1}{2} + \frac{(X_2 + X_3 + \dots + X_m)}{m} + \frac{X_m + 1}{2}$$

$$SV = \frac{X_i}{\bar{X}_i}$$

where \bar{X}_c = centered moving average

m = number of elements in the centered moving average

SV = seasonal variation factor

X_i = value of the ith data point

\bar{X}_i = centered moving average of the data point

Example:

Econo-Wise Home Appliance Company's monthly sales for the last 15 months are:

<u>Month</u>	<u>Sales (\$K)</u>	<u>Month</u>	<u>Sales (\$K)</u>
1	397	9	513
2	376	10	434
3	460	11	562
4	501	12	593
5	455	13	579
6	390	14	601
7	530	15	598
8	560		

Find the centered 12-month moving average and seasonal variation factor for months 7-9.

MULTIPLE LINEAR REGRESSION

This program performs a least squares multiple linear regression for a series of data points x , y , z . Linear regression is a statistical method for finding a straight line that best fits a set of data points. The equation of this straight line expresses the linear relationship between independent (x and y) and dependent (z) variables and is of the form:

$$z = a + bx + cy$$

The three variables are input by pressing [A]. If one or more of the data points was entered incorrectly, simply re-enter the incorrect value(s) and press [///] [A]. Then continue as before. The three coefficients (a , b , c) are calculated by pressing [B].

In addition, the program also calculates the coefficient of determination r^2 ([C]). This is an indication of the "goodness of fit" for the calculated straight line, and is a number between 0 and 1. Values closer to 1 indicate "better" fits than values closer to 0.

Having determined the equation (the [B] key), the user can then project estimates of z for given x , y values ([D]). The sums ($\sum x_i$; $\sum y_i$; $\sum z_i$), the sums of squares ($\sum x_i^2$; $\sum y_i^2$; $\sum z_i^2$), and the sums of cross products ($\sum x_i y_i$; $\sum x_i z_i$; $\sum y_i z_i$) are stored in registers 07-09, 04-06, and 01-03 respectively.

Equations:

$$z = a + bx + cy$$

$$\sum z_i = an + b\sum x_i + c\sum y_i \quad i = 1, 2, \dots, n$$

$$\sum x_i z_i = a\sum x_i + b\sum x_i^2 + c\sum x_i y_i$$

$$\sum y_i z_i = a\sum y_i + b\sum x_i y_i + c\sum y_i^2$$

$$c = \frac{A - B}{[n\sum x_i^2 - (\sum x_i)^2] [n\sum y_i^2 - (\sum y_i)^2] - [n\sum x_i y_i - (\sum x_i)(\sum y_i)]^2}$$

where:

$$A = [n\sum x_i^2 - (\sum x_i)^2] [n\sum y_i z_i - (\sum y_i)(\sum z_i)]$$

$$B = [n\sum x_i y_i - (\sum x_i)(\sum y_i)] [n\sum x_i z_i - (\sum x_i)(\sum z_i)]$$

$$b = \frac{[n\sum x_i z_i - (\sum x_i)(\sum z_i)] - c[n\sum x_i y_i - (\sum x_i)(\sum y_i)]}{n\sum x_i^2 - (\sum x_i)^2}$$

$$a = \frac{1}{n} (\sum z_i - c \sum y_i - b \sum x_i)$$

$$R^2 = \frac{a \sum z_i + b \sum x_i z_i + c \sum y_i z_i - \frac{1}{n} (\sum z_i)^2}{(\sum z_i^2) - \frac{(\sum z_i)^2}{n}}$$

Example:

A commercial land appraiser has examined 5 vacant lots in the downtown section of a local community, all of which have different depths, frontages, and values as shown below. Based on this data, what is the relationship between depth, frontage, and lot value? What is the coefficient of determination? What predicted value would a lot have with 50 foot depth and 70 foot frontage? With a 75 foot depth and 80 foot frontage?

<u>Lot Depth (feet)</u>	<u>Lot Frontage (feet)</u>	<u>Lot Value</u>
70	70.8	\$101,000
90	60.0	82,190
85	90.0	170,000
40	70.0	100,000

NORMAL, INVERSE NORMAL, t AND F DISTRIBUTIONS

These programs evaluate the standard normal density function $f(x)$, the normal integral $Q(x)$ for a given x and the cumulative distribution $P(x)$ for a given x and degrees of freedom ν , and the integral of the F distribution for given values of x .

Equations:

1. Standard normal density

$$f(x) = \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}}$$

2. Normal integral

$$Q = \frac{1}{\sqrt{2\pi}} \int_x^{\infty} e^{-\frac{t^2}{2}} dt.$$

(Solving for x given Q as the inverse normal distribution)

3. t density function

$$f(x) = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\sqrt{\pi\nu} \Gamma\left(\frac{\nu}{2}\right)} \left(1 + \frac{x^2}{\nu}\right)^{-\frac{\nu+1}{2}}$$

4. Cumulative distribution function

$$P(x) = \int_{-\infty}^x f(y) dy$$

5. F distribution

$$P(x) = \int_x^{\infty} \frac{\Gamma\left(\frac{\nu_1 + \nu_2}{2}\right) y^{\frac{\nu_1}{2} - 1} \left(\frac{\nu_1}{\nu_2}\right)^{\frac{\nu_1}{2}}}{\Gamma\left(\frac{\nu_1}{2}\right) \Gamma\left(\frac{\nu_2}{2}\right) \left(1 + \frac{\nu_1}{\nu_2} y\right)^{\frac{\nu_1 + \nu_2}{2}}} dy$$

Reference:

Abramowitz and Stegun, Handbook of Mathematical Functions, National Bureau of Standards, 1970.

Example 1: (Program 1)

Using normal distribution, find $f(x)$ and $Q(x)$ for $x = 1.18$.

Keystrokes:	Display:
[USER]	(set USER mode)
[XEQ] [ALPHA] SIZE [ALPHA] 016	
[XEQ] [ALPHA] NORMAL [ALPHA]	0.0000
1.18 [A]	F=0.1989 (f(1.18))
1.18 [B]	Q=0.1190 (Q(1.18))

Example 2: (Program 2)

Using t distribution, find $f(x)$ and $P(x)$ for $x = 2.2$, $v = 11$.

Keystrokes:	Display:
[USER]	(set USER mode)
[XEQ] [ALPHA] SIZE [ALPHA] 013

BASIC STATISTICS FOR TWO VARIABLES

This program calculates means, standard deviations, covariance, correlation coefficient, and coefficients of variation from ungrouped data points $[(x_i, y_i), i=1, 2, \dots, n]$ or grouped data points $[(x_i, y_i, f_i), i=1, 2, \dots, n]$. f_i denotes the frequency of repetition of (x_i, y_i) .

Equations:

$$\text{Mean} \quad \bar{x} = \frac{1}{n} \sum_{i=1}^n x_i \quad \bar{y} = \frac{1}{n} \sum_{i=1}^n y_i$$

Standard deviation

$$s_x = \sqrt{\frac{\sum x_i^2 - n\bar{x}^2}{n-1}}$$

$$s_x' = \sqrt{\frac{\sum x_i^2 - n\bar{x}^2}{n}}$$

$$s_y = \sqrt{\frac{\sum y_i^2 - n\bar{y}^2}{n-1}}$$

$$s_y' = \sqrt{\frac{\sum y_i^2 - n\bar{y}^2}{n}}$$

covariance

$$s_{xy} = \frac{1}{n-1} (\sum x_i y_i - \frac{1}{n} \sum x_i \sum y_i)$$

$$s_{xy}' = \frac{1}{n} (\sum x_i y_i - \frac{1}{n} \sum x_i \sum y_i)$$

correlation coefficient

$$\gamma_{xy} = \frac{s_{xy}}{s_x s_y}$$

coefficients of variation

$$V_x = \frac{s_x}{\bar{x}} \cdot 100, \quad V_y = \frac{s_y}{\bar{y}} \cdot 100$$

Note: n is a positive integer > 1 .

Example:

For the following set of data, find the means, standard deviations, covariance, correlation coefficient and coefficients of variation.

x_i	4.8	5.2	4.1	3.8
y_i	15.1	11.5	13.6	14.3
f_i	1	3	2	1

MOVING AVERAGE

In a moving average, a specified number of data points are averaged. When there is a new piece of input data, the oldest piece of data is discarded to make room for the latest input. This replacement scheme makes the moving average a valuable tool in following trends. The fewer the number of data points, the more trend sensitive the average becomes. With a large number of data points, the average behaves more like a regular average, responding slowly to new input data.

This program allows for a moving average of 14 points with no memory modules and 64 more points with each additional memory module. It also allows for more than one moving average to be computed with the same set of data. For example, instead of obtaining only a 6 month moving average, you could obtain a 3 month and 12 month as well with the same data. For each additional moving average you wish to compute, the maximum number of data points is reduced by three. For example if you have no memory modules and wish to compute 2 moving averages with the same data, the maximum size for an average is 11.

This program is most useful when a card reader is available. With data card(s) to remember your old data points you need only input the most recent data point to compute current moving average(s).

Example 1:

A six period and three period moving average is desired to project monthly sales. The first 6 months of sales follows:

<u>Month</u>	<u>1</u>	<u>2</u>	<u>3</u>	<u>4</u>	<u>5</u>	<u>6</u>
Sales	125	183	207	222	198	240

Compute the 3 month moving average for months 3,4,5, and 6, and the 6 month moving average for month 6.

Keystrokes:

[XEQ] [ALPHA] SIZE [ALPHA] 006
 [XEQ] [ALPHA] AVG [ALPHA]
 2 [R/S]
 6 [R/S]
 [XEQ] [ALPHA] SIZE [ALPHA] 015 [R/S]

Now record the data for example 2.

[XEQ] [ALPHA] UPDATE [ALPHA] RDY 01 OF 01
 Insert one side of the data card into the card reader.

Now turn the calculator off assume a month has passed. Turn the calculator on and load the program.

Example 2:

The actual sales for the seventh month totaled 225 units. Compute new moving averages and output the current points in the averages.

GOMPERTZ CURVE TREND ANALYSIS

A useful curve for evaluating sales trends, etc., is the Gompertz curve. This is a "growth" curve having a general "S" shape and may be used to describe series of data where the early rate of growth is small, then accelerates for a period of time and then slows again as the time grows long. The sales curves for many products follow this trend during the introductory, growth and early mature phases.

The data points to be fit to a Gompertz curve should be equally spaced along the X (or time) axis and all the data points must be positive. The points are divided serially into 3 groups for data entry.

This program processes the data, fits it to a Gompertz curve and calculates estimated values for future data points. The 3 constants (a,b,c) which characterize the curve are available if desired.

Equations:

$$y = ca^x b^x \quad \text{where } a, b, c, x, \text{ and } y \text{ are positive}$$

$$b = \left(\frac{s_3 - s_2}{s_2 - s_1} \right)^{1/n}$$

$$c = \exp \left[\frac{1}{n} \left(\frac{s_1 s_3 - s_2^2}{s_1 + s_3 - 2s_2} \right) \right]$$

$$a = \exp \left[\frac{(b-1)(s_2 - s_1)}{b(b^{n-1})^2} \right]$$

where $s_1, s_2,$ and s_3 are:

$$s_1 = \sum_{i=1}^n \ln y_i = n \ln c + b \ln a \frac{b^n - 1}{b - 1}$$

$$s_2 = \sum_{i=n+1}^{2n} \ln y_i = n \ln c + b^{n+1} \ln a \frac{b^n - 1}{b - 1}$$

$$s_3 = \sum_{i=2n+1}^{3n} \ln y_i = n \ln c + b^{2n+1} \ln a \frac{b^n - 1}{b - 1}$$

Example:

The X-Presso Company marketed a revolutionary new coffee brewing machine in 1968. Sales grew at a steady pace for several years then began to slow. The sales records for the first 9 years of the product's life were as follows:

<u>Year</u>	<u>Sales (\$K)</u>	<u>Year</u>	<u>Sales (\$K)</u>
1	18	6	260
2	41	7	282
3	49	8	322
4	151	9	340
5	188		

What are the projected sales volumes for this product in its 10th and 12th year? What is the maximum yearly sales volume for this product if the present trend continues? What annual sales rate would the curve have predicted for the 5th year of the product's life? (Arrange the data as follows)

Group I	Group II	Group III
18	151	282
41	188	322
49	260	340

BREAK-EVEN ANALYSIS

Break-even analysis is a technique for analyzing the relationships among fixed costs, variable costs, and income. Until the break-even point is reached, at the intersection of the total income and total cost lines, the producer operates at a loss. After the break-even point, each unit produced and sold makes a profit. Break-even analysis may be represented as follows:

Given four of the following variables: fixed costs (F), sales price per unit (P), variable costs per unit (V), number of units sold (U), and gross profit (GP), this program evaluates the remaining variable. To calculate the break-even values, simply let the gross profit equal zero.

The degree of operating leverage (OL) at a point is defined as the ratio of the percentage change in net operating income to the percentage change in units sold. The greatest degree of operating leverage is found near the break-even point, where a small change in sales may produce a very large increase in profits. This happens because the profits are close to zero near the break-even point. Likewise, firms with a small degree of operating leverage are operating farther from the break-even point, and they are relatively insensitive to changes in sales volume.

The necessary inputs to calculate the degree of operating leverage are fixed costs (F), sales price per unit (P), variable costs per unit (V), and number of units (U).

For subsequent calculations, it is necessary only to input new data.

Break Even Analysis

$$GP = U(P-V) - F$$

$$OL = \frac{U(P-V)}{U(P-V) - F}$$

Example 1: The Cooper Company sells finance textbooks at \$13 each. Given costs and revenues below, how many textbooks must be sold to break even?

FIXED COSTS	
Typesetting	\$ 4,000
Graphics production	5,000
Printing and binding	<u>3,000</u>
Total fixed costs	<u>\$12,000</u>
VARIABLE COSTS PER COPY	
Distribution	\$ 1.00
Commissions	3.75
Royalties	<u>2.00</u>
Total variable costs per copy	<u>\$ 6.75</u>
Sales price per copy	<u>\$13.00</u>

Example 2: What is the Cooper Company's degree of operating leverage at 2000 units? At 5000 units?

EXPERIENCE (LEARNING) CURVE FOR MANUFACTURING COST

Many production process costs vary with output in close relation to the learning curve:

$$C_n = C_1 n^{\log r / \log 2}$$

where C_1 is the cost of the first unit produced
 C_n is the cost of the nth unit produced
 n is the number of units produced
 r is the learning factor

This program solves for any of the above variables and also solves for the average cost over a range from i to j using the formula:

$$\bar{C}_n = \frac{C_1}{j-i} \frac{j^{B+1} - i^{B+1}}{B+1}$$

where $B = \log r / \log 2$

The theory applies to a single product, or closely related series of similar products developing through the evolutionary process. The average cost is approximate because of the finite, discrete nature of the function. Small values of i may produce incorrect results.

Example:

A computer manufacturer begins a pilot run on a component. Cost accounting informs him that the first unit off of the line cost \$975 and the 100th unit a week later costs \$643. What cost can the manufacturer expect for the 10,000th unit of the line? What is the average cost of the 10,000 units?

PRICE ELASTICITY OF DEMAND

Using historical (or estimated) prices and resulting unit sales, this program calculates the elasticity of demand (elasticity of quantity sold with respect to a change in price).

Equations:

$$E_d = \frac{\Delta Q}{\frac{1}{2}(Q_i + Q_{i+1})} \quad \frac{\Delta P}{\frac{1}{2}(P_i + P_{i+1})}$$

where:

E_d = demand elasticity

Q_{i+1} = quantity sold after price change

Q_i = quantity sold before price change

P_{i+1} = new price

P_i = old price

i = 1, 2, 3, ..., n

ΔQ = $Q_{i+1} - Q_i$

ΔP = $P_{i+1} - P_i$

$$\frac{\Delta P}{\frac{1}{2}[P_i + P_{i+1}]} \neq 0$$

Example:

The sales volume of a product varied with the different price changes per unit as follows:

<u>N</u>	<u>Quantity sold (Q)</u>	<u>Price/Unit (P)</u>
1	0	6
2	10	4
3	20	2
4	30	0*

Compute the price elasticity of demand.

*hypothetical price for simplicity

Hewlett-Packard Software

In terms of power and flexibility, the problem-solving potential of the HP-41C programmable calculator is nearly limitless. And in order to see the practical side of this potential, HP has different types of software to help save you time and programming effort. Every one of our software solutions has been carefully selected to effectively increase your problem-solving potential. Chances are, we already have the solutions you're looking for.

Application Pacs

To increase the versatility of your HP-41C, HP has an extensive library of "Application Pacs". These programs transform your HP-41C into a specialized calculator in seconds. Included in these pacs are detailed manuals with examples, miniature plug-in Application Modules, and keyboard overlays. Every Application Pac has been designed to extend the capabilities of the HP-41C.

You can choose from:

**Aviation
Clinical Lab
Circuit Analysis
Financial Decisions
Mathematics**

**Structural Analysis
Surveying
Securities
Statistics
Stress Analysis
Games**

**Home Management
Machine Design
Navigation
Real Estate
Thermal and Transport Science**

Users' Library

The Users' Library provides the best programs from contributors and makes them available to you. By subscribing to the HP-41C Users' Library you'll have at your fingertips literally hundreds of different programs from many different application areas.

*** Users' Library Solutions Books**

Hewlett-Packard offers a wide selection of Solutions Books complete with user instructions, examples, and listings. These solution books will complement our other software offerings and provide you with a valuable tool for program solutions.

You can choose from:

**Business Stat/Marketing/Sales
Home Construction Estimating
Lending, Saving and Leasing
Real Estate
Small Business
Geometry
High-Level Math
Test Statistics
Antennas
Chemical Engineering
Control Systems
Electrical Engineering
Fluid Dynamics and Hydraulics**

**Civil Engineering
Heating, Ventilating & Air Conditioning
Mechanical Engineering
Solar Engineering
Calendars
Cardiac/Pulmonary
Chemistry
Games
Optometry I (General)
Optometry II (Contact Lens)
Physics
Surveying**

* Some books require additional memory modules to accommodate all programs.

BUSINESS STATISTICS/MARKETING SALES

FORECASTING USING EXPONENTIAL SMOOTHING
MONTHLY SEASONAL VARIATION FACTORS BASED ON CENTERED
MOVING AVERAGES
MULTIPLE LINEAR REGRESSION
NORMAL, INVERSE NORMAL, T AND F DISTRIBUTIONS
BASIC STATISTICS FOR TWO VARIABLES
MOVING AVERAGE
GOMPERTZ CURVE TREND ANALYSIS
BREAK-EVEN ANALYSIS
EXPERIENCE (LEARNING) CURVE FOR MANUFACTURING COST
PRICE ELASTICITY OF DEMAND

**HEWLETT
PACKARD**
